Abstract

This paper proposes a group theory-based optimization algorithm (GTOA) for knapsack problems, which draws algebraic group operations into the evolution process. The key parts of GTOA are that the feasible solution of the knapsack problem is considered as an element of the direct product of groups and that the evolution process is implemented by multiplication and inverse operations of the direct product of groups. Based on the algorithms for handling infeasible solutions, GTOA is used to solve knapsack problems such as the Set-union knapsack problem, the Discounted {0-1} knapsack problem, and the Bounded knapsack problem. GTOA is validated to be an efficient algorithm for solving knapsack problems. A comparison between GTOA and existing evolutionary algorithms such as genetic algorithm, binary particle swarm optimization, binary artificial bee colony, and their improved variations is conducted and the comparative results show that GTOA has a better performance than other algorithms. In addition, GTOA is not only an efficient algorithm for solving knapsack problems but is also the first paradigm that applies group theory to directly design an evolutionary algorithm.

Keywords: Evolutionary algorithms, combinatorial optimization,

additive group, direct product, knapsack problems.

1. Introduction

Knapsack problems (KPs)[1,2] are classical NP-complete problems and important combinatorial optimization problems as well. Modeling and solving KPs has great theoretical significance and practical value in many fields such as resource allocations, capital budgets, investment decisions, industrial loading, economy and finance, and information security[3,4]. The classic knapsack problem is the 0-1 knapsack problem (0-1KP), and there exist many extensions of 0-1KP such as the bounded knapsack problem (BKP), the unbounded knapsack problem (UKP), the multidimensional knapsack problem (MDKP), the multiple knapsack problem (MKP), the quadratic knapsack problem (QKP), the set-union knapsack problem (SUKP), the discounted {0-1} knapsack problem (D{0-1}KP), the randomized time-varying knapsack problem (RTVKP), the quadratic multiple knapsack problem (QMKP), and the multiple-choice multidimensional knapsack problem (MMKP) [3,5-10]. Though there are many members of the KPs-family, they can be divided into three categories according to their representation of feasible solutions.

The feasible solution of the first category of KPs can be represented as an n -dimensional 0-1 vector $Y = (y_1, y_2, \dots, y_n) \in \{0, 1\}^n$, where n is the number of items in KPs. Obviously, 0-1KP, MDKP, QKP, D{0-1}KP, SUKP, and RTVKP all belong to the first category of KPs. The second category of KPs use an n -dimensional integer vector $Y = (y_1, y_2, \dots, y_n) \in \{0, 1, \dots, m\}^n$ to represent a feasible solution, where n is the number of items in KPs, m is an integer and $m \geq 2$. MKP, QMKP, and D{0-1}KP all belong to the second category of KPs. Note that D{0-1}KP belongs to the first and second category of KPs simultaneously. The feasible solution of third category of KPs is an n -dimensional integer vector $Y = (y_1, y_2, \dots, y_n) \in \{0, 1, \dots, m_1\} \times \{0, 1, \dots, m_2\} \times \dots \times \{0, 1, \dots, m_n\}$, where n is the number of items in KPs, and m_1, m_2, \dots, m_n are n positive integers in which at least two values are not equal. BKP, UKP, and MMKP all belong to

the third category of KPs.

30 For solving KPs, there are many algorithms which can be mainly divided into two categories. One category consists of deterministic algorithms including dynamic programming, backtracking, and branch and bound [11,12]. The other category is non-deterministic algorithms which contains randomized algorithms, approximation algorithms, biological algorithms, and evolutionary
35 algorithms [2,13-15]. Since there do not exist polynomial time deterministic algorithms to solve KPs, non-deterministic algorithms are more suited to quickly and approximately solve the KPs in practical applications.

Evolutionary algorithms (EAs) [15,16] have been well recognized as algorithms with swarm intelligence, which are essentially stochastic approximations.
40 Their main advantage is that they do not need to calculate the derivatives and gradients of the objective function, do not require the objective function to be continuous, and do have the inherent implicit parallelism and the strong ability to search for global optimization as well. The most classic EAs include the genetic algorithm (GA) [17], particle swarm optimization (PSO) [18], differential
45 evolution (DE) [19], harmony search algorithm (HS) [20], artificial fish swarm (AFS) [21], ant colony optimization (ACO) [22], and artificial bee colony (ABC) [23]. In recent years, EAs have had many successful applications in solving optimization problems, such as numerical optimization problems [24,25], knapsack problems [26], satisfiability problems [27], and set cover problems [28], which
50 attract the great attention of scholars in many fields. Currently, by simulating behaviors of biological colonies in nature or learning from some phenomena of social activities, researchers have put forward many new EAs consecutively, such as the firefly algorithm (FFA) [29], the sine cosine algorithm (SCA) [30], the symbiotic organisms search (SOS) [31], the grey wolf optimizer (GWO) [32], and
55 teaching-learning-based optimization (TLBO) [33]. Although nature provides us with endless inspiration, it is not perfect to design EAs solely based on bionic thought. In addition, the performance of many newly proposed EAs is not better than the classic ones, which accords with the No Free Lunch Theorem [34]. It is well known that, except for GA and ACO, almost existing EAs were ini-

60 tially put forward to solve numerical optimization problems and they generally
could not be applied to directly solve combinatorial optimization problems. The
methods proposed in the literature [35-37] that modify the evolution operator
to fit to solve problems and in the literature [38,39] that map a real vector to
a potential solution of problem are suitable only for the first category of KPs,
65 not for the second and third ones.

Recently, the literatures [40,41] has used permutation group to improve the
existing evolutionary algorithms, which are given an abstract algebraic differ-
ential mutation of DE and a vector operations of PSO, respectively, and used
them to provide approaches to solving permutation problems. In fact, group
70 theory not only can be used to improve the existing evolutionary algorithms,
but also can be used to directly design a new evolutionary algorithm. In this
paper, we will take the knapsack problems as an example to illustrate how to
design a new evolutionary algorithm by using the direct product of groups which
is generated by the additive group of $\mathbf{Z}/n\mathbf{Z}$, the integers modulo n , where \mathbf{Z} is
75 the integer set. From the point of view of algebra, we can see that no matter
which category the KPs belong to, each dimensional component of its feasible
solutions can be considered as an element in the additive group of $\mathbf{Z}/n\mathbf{Z}$ which
can be simplified as $\mathbf{Z}_n = \{0, 1, \dots, n-1\}$, where n is a positive integer and
 $n \geq 2$. Based on the abovementioned observation, an algebraic methodology for
80 designing EAs is presented, and a Group Theory-based Optimization Algorithm
(GTOA) is proposed by applying the direct product of groups. GTOA has a
universal property and is suitable for solving KPs. The computations of SUKP,
D{0-1}KP, and BKP illustrate that GTOA is not only easy to implement but
also highly efficient. Moreover, GTOA is also a successful example of algorithm
85 design based on group theory.

2. The proposed Group Theory-based Optimization Algorithm

2.1. Group and Direct Product of Groups

The following is a brief introduction to the basic concepts and terminologies of the group and direct product of groups. More details can be found from literatures [42,43].

Let G be a nonempty set, and let $*$ be a binary operation on G , if

- (1) $\forall a, b \in G, a * b \in G$;
- (2) $\forall a, b, c \in G, (a * b) * c = a * (b * c)$;
- (3) $\forall a \in G, \exists e \in G, a * e = e * a = a$;
- (4) $\forall a \in G, \exists b \in G, a * b = b * a = e$, then $(G, *)$ is a group.

Henceforth, we shall write ab instead of $a * b$ and G instead of $(G, *)$. We call e the identity of G and, if $ab = ba = e$, then we call b the inverse of a , denoted by a^{-1} . It is clear that the inverse of e is itself.

Let G be a group, $a \in G$, and let i be an integer. Then, the i th power a^i of a is defined as following:

$$a^i = \begin{cases} a^{i-1}a, & \text{if } i > 0 ; \\ e, & \text{if } i = 0 ; \\ (a^{-1})^{-i}, & \text{if } i < 0 . \end{cases} \quad (1)$$

Let $\mathbf{Z}_n = \{0, 1, \dots, n-1\}$, n is a positive integer and $n \geq 2$. We define a binary operation \oplus on \mathbf{Z}_n as follows:

$$\forall a, b \in \mathbf{Z}_n, a \oplus b = (a + b)(mod n). \quad (2)$$

where $+$ is a common addition operator, $x(mod n)$ denotes the remainder when x is divided by n .

It is easy to see that \mathbf{Z}_n is a group for operation \oplus , and its identity is 0. We denote $-a$ as the inverse of a in \mathbf{Z}_n . Then, $-0=0$, and, if $a \neq 0$ then $-a = n - a$.

If G_1, G_2, \dots, G_k are k groups, then their direct product, denoted by $G_1 \times G_2 \times \dots \times G_k$, is the group with elements that are all ordered k tuple (a_1, a_2, \dots, a_k) , where $a_i \in G_i (i = 1, 2, \dots, k)$, and with operation

$$(a_1, \dots, a_k)(b_1, \dots, b_k) = (a_1b_1, \dots, a_kb_k). \quad (3)$$

110 It is easy to check that $G_1 \times G_2 \times \dots \times G_k$ is a group: the identity is (e_1, e_2, \dots, e_k) where e_i is the identity of G_i ($i = 1, 2, \dots, k$) and the inverse $(a_1, a_2, \dots, a_k)^{-1}$ is $(a_1^{-1}, a_2^{-1}, \dots, a_k^{-1})$.

Let $\mathbf{Z}_{n_i} = \{0, 1, \dots, n_i - 1\}$, where n_i is a positive integer and $n_i \geq 2$, $i = 1, 2, \dots, k$. Then, $\mathbf{Z}_{n_1} \times \mathbf{Z}_{n_2} \times \dots \times \mathbf{Z}_{n_k}$ is a direct product of groups, 115 denoted by $\mathbf{Z}[n_1, n_2, \dots, n_k]$. It is clear that $(0, 0, \dots, 0)$ is the identity, and the inverse of (a_1, a_2, \dots, a_k) is $-(a_1, a_2, \dots, a_k)$, and

$$-(a_1, a_2, \dots, a_k) = (-a_1, -a_2, \dots, -a_k). \quad (4)$$

where $-a_i$ is the inverse of a_i in \mathbf{Z}_{n_i} . $\forall (a_1, a_2, \dots, a_k), (b_1, b_2, \dots, b_k) \in \mathbf{Z}[n_1, n_2, \dots, n_k]$, we have

$$(a_1, \dots, a_k) \oplus (b_1, \dots, b_k) = (a_1 \oplus b_1, \dots, a_k \oplus b_k). \quad (5)$$

The i th power of (a_1, a_2, \dots, a_k) is $i(a_1, a_2, \dots, a_k)$, where i is an integer.

120 It is easy to see that $\mathbf{Z}[2, 2, \dots, 2] = \{0, 1\}^n$, $\mathbf{Z}[m+1, m+1, \dots, m+1] = \{0, 1, \dots, m\}^n$ and $\mathbf{Z}[m_1+1, m_2+1, \dots, m_n+1] = \{0, 1, \dots, m_1\} \times \{0, 1, \dots, m_2\} \times \dots \times \{0, 1, \dots, m_n\}$.

2.2. Group Theory-Based Optimization Algorithm

It is easy to see that the feasible solutions of the first category of KPs 125 are the elements in the direct product of groups $\mathbf{Z}[2, 2, \dots, 2]$; those of the second category are the elements in $\mathbf{Z}[m+1, m+1, \dots, m+1]$; and those of the third category are the elements in $\mathbf{Z}[m_1+1, m_2+1, \dots, m_n+1]$. We notice that $\mathbf{Z}[2, 2, \dots, 2]$ and $\mathbf{Z}[m+1, m+1, \dots, m+1]$ are special cases of $\mathbf{Z}[m_1+1, m_2+1, \dots, m_n+1]$, respectively. Hence, the basic principle and 130 the pseudo-code of GTOA will be described by applying the direct product $\mathbf{Z}[m_1+1, m_2+1, \dots, m_n+1]$.

Suppose that $Y = (y_1, y_2, \dots, y_n)$, $V = (v_1, v_2, \dots, v_n)$, $W = (w_1, w_2, \dots, w_n)$ are three different elements randomly selected from $\mathbf{Z}[m_1+1, m_2+1, \dots, m_n+1]$. A new element $X = (x_1, x_2, \dots, x_n) \in \mathbf{Z}[m_1+1, m_2+1, \dots, m_n+1]$ is gener- 135 ated by manipulating a group operation on Y, V, W according to the following

equation:

$$X = Y \oplus (F(V \oplus (-W))). \quad (6)$$

where $x_j = y_j \oplus [f_j(v_j \oplus (m_j + 1 - w_j))]$, $j = 1, 2, \dots, n$; $F = (f_1, f_2, \dots, f_n)$ is an n -dimensional random vector in $\{-1, 0, 1\}^n$, which is called the Combinatorial Factor Vector. Since formula (6) is similar to the representation of a straight-line equation, we call it the Random Linear Combination Operator (RLCO). 140

It is worth to note that RLCO uses three different random elements to produce a new element on the space $\mathbf{Z}[m_1 + 1, m_2 + 1, \dots, m_n + 1]$, which indicates it is not only a random operation but has the characteristic of learning from other elements. Therefore, RLCO is a global random search operator and exhibits the global exploration ability by learning from others. However, it is not enough for an evolutionary algorithm to only have the global exploration ability. An excellent evolutionary algorithm should make a trade-off between exploration and exploitation, which are both indispensable factors for an evolutionary algorithm to work efficiently. In the following, we propose a local search operator over the space $\mathbf{Z}[m_1 + 1, m_2 + 1, \dots, m_n + 1]$ based on the inverse operation, which is named the Inversion and Random Mutation Operator (IRMO). 145

Let $X = (x_1, x_2, \dots, x_n) \in \mathbf{Z}[m_1 + 1, m_2 + 1, \dots, m_n + 1]$ and $m_i \geq 1$ ($i = 1, 2, \dots, n$), P_m be the mutation probability of IRMO. Then, the pseudo-code of IRMO is described as below. 150

Algorithm 1. IRMO

Input: $X = (x_1, x_2, \dots, x_n)$, Mutation probability P_m .

Output: The mutated $X = (x_1, x_2, \dots, x_n)$.

```

1 for  $i \leftarrow 1$  to  $n$  do
2   if ( $rand_1 < P_m$ ) then
3     if ( $rand_2 \leq 0.5 \wedge x_i \neq 0$ ) then  $x_i \leftarrow m_i + 1 - x_i$  ;
4     else  $x_i \leftarrow rand([0, m_i] - \{x_i\})$ ;
5   end if
6 end for
```

160

165 In IRMO, $rand_1$ and $rand_2$ are two random numbers in the interval $(0, 1)$; the mutation probability P_m satisfies $0 < P_m \leq 0.5$; $rand([0, m_i] - \{x_i\})$ represents a random integer that is not equal to x_i in $[0, m_i]$. It is obvious that the probabilities of obtaining the inverse mutation (Step3) and the random mutation (Step4) are equal. The time complexity of IRMO is $O(n)$.

170 In addition, in group $Z_2 = \{0, 1\}$ under modulo 2, since $-0 = 0$ and $-1 = 1$, the IRMO does not work for 0-1 vectors in the search space $Z[2, 2, \dots, 2]$. Drawing lessons from the mutation operator of GA [17], a local search operator suitable for the space $Z[2, 2, \dots, 2]$ is proposed, we name it the Switch Mutation Operator (SMO).

175 Let $X = (x_1, x_2, \dots, x_n) \in Z[2, 2, \dots, 2]$ and P_m be the mutation probability of SMO. Then, the pseudo-code of SMO is described as follow:

Algorithm 2. SMO

Input: $X = (x_1, x_2, \dots, x_n)$, Mutation probability P_m .

Output: The mutated $X = (x_1, x_2, \dots, x_n)$.

180 1 for $i \leftarrow 1$ to n do
 2 if ($rand \leq P_m$) then $x_i \leftarrow 1 - x_i$;
 3 end for

In SMO, $rand$ is a random number in $(0, 1)$, and the mutation probability P_m satisfies $0 < P_m \leq 0.5$. It is easy to see that the time complexity of SMO is 185 $O(n)$.

Let $P(t) = \{X_i(t) \mid 1 \leq i \leq NP\}$ be the t -th generation population of GTOA, where $X_i(t) = (x_{i1}(t), x_{i2}(t), \dots, x_{in}(t)) \in Z[m_1 + 1, m_2 + 1, \dots, m_n + 1]$ is the i -th individual, NP is the size of the population, t is an integer and $t \geq 0$. $Fit(X_i(t))$ denotes the fitness of the individual $X_i(t)$ and its computation 190 generally relies on the objective function. Let $B = (b_1, b_2, \dots, b_n) \in Z[m_1 + 1, m_2 + 1, \dots, m_n + 1]$ be the best individual in $P(MIT)$, MIT be the number of maximum iterations, and $Y = (y_1, y_2, \dots, y_n) \in Z[m_1 + 1, m_2 + 1, \dots, m_n + 1]$ be an n -dimensional vector. For the KPs with the objective function $Maxf(X)$, the pseudo-code of GTOA is described as follows:

195 **Algorithm 3. GTOA**

Input: An instance of KPs; Parameters NP , MIT , m_1, m_2, \dots, m_n ; Mutation probability P_m .

Output: An approximate solution (or optimal solution) B and $f(B)$.

```

1 Generate initial population  $\mathbf{P}(0) = \{X_i(0) \mid 1 \leq i \leq NP\}$  randomly;
200 2 Compute  $Fit(X_i(0))$ ,  $1 \leq i \leq NP$ , and  $t \leftarrow 0$ 
3 while ( $t < MIT$ ) do
4   for  $i \leftarrow 1$  to  $NP$  do
5      $Y \leftarrow X_{p_1}(t) \oplus (F(X_{p_2}(t) \oplus (-X_{p_3}(t))))$ ;
6      $Y \leftarrow \mathbf{IRMO}(Y, P_m)$ ; (or  $Y \leftarrow \mathbf{SMO}(Y, P_m)$ );
205 7     if  $Fit(Y) > Fit(X_i(t))$  then  $X_i(t+1) \leftarrow Y$ ;
8     else  $X_i(t+1) \leftarrow X_i(t)$ ;
9   end for
10  Generate  $\mathbf{P}(t+1)$ , and  $t \leftarrow t+1$ ;
11 end while
210 12 Determine  $B$  in  $\mathbf{P}(MIT)$ ;
13 return  $(B, f(B))$  .
```

In Step 5 of GTOA, a temporary individual $Y = (y_1, y_2, \dots, y_n) \in \mathbf{Z}[m_1 + 1, m_2 + 1, \dots, m_n + 1]$ is generated by the RLCO operator, where $X_{p_1}(t)$, $X_{p_2}(t)$ and $X_{p_3}(t)$ are three different individuals randomly selected from the t -th generation population $\mathbf{P}(t)$. The individual Y is mutated by SMO in Step 6 when solving the first category of KPs and by IRMO when solving those in the second and third categories. Noting that both MIT and NP are multiples of n , the time complexity of GTOA is $O(MIT * n * NP) = O(n^3)$, which indicates that GTOA is a stochastic approximation algorithm.

220 3. Solving Knapsack Problems by GTOA

To illustrate the effectiveness and wide application range of GTOA, we select three typical knapsack problems, i.e., SUKP, D{0-1}KP, and BKP, and use GTOA to solve them. Since these three problems are constrained optimization problems, their infeasible solutions will be unavoidably generated during

225 GTOA's solving process. At present, there are several common methods for
 handling infeasible solutions, such as the Penalty function approach, the Re-
 pair approach, the Purist approach, the Separation approach, and the Hybrid
 approach [44-49]. Existing studies show that the greedy strategy-based repair
 and optimization methods are the best fit for KPs [9,15,44,45]. According to
 230 the mathematical model of KPs and the greedy strategy-based repair and op-
 timization method, we will present the efficient approaches to solving KPs by
 using GTOA.

3.1. Solving Set Union Knapsack Problem by GTOA

The SUKP [7,50], belonging to the first category of KPs, has important
 235 application in investment decision-making, flexible manufacturing systems, the
 database system with primary, and secondary memories [3,7,51]. Goldschmidt
 et al.[7] first used hyper graph to propose a deterministic algorithm for solving
 SUKP based on dynamic programming, but its time complexity is exponential,
 which leads to very poor practicability. By means of the d -regular graph theory,
 240 Ashwin Arulsevan [50] proposed an approximation algorithm A-SUKP with the
 approximation ratio of $\frac{1}{(1-e^{-\frac{1}{d}})}$ based on the greedy strategy, where $d(d \geq 2)$ is
 the supremum of the frequencies of all elements. A-SUKP greatly improved the
 speed for solving SUKP. Yichao He et al.[44] proposed a novel binary artificial
 bee colony (BABC) to solve SUKP and conducted a comparison with A-SUKP
 245 showing the BABC not only has a better performance but is also faster.

Definition of SUKP: Given a set of elements $U = \{1, 2, \dots, m\}$ and a set
 of items $S = \{1, 2, \dots, n\}$, where each item $i \in S$ corresponds to a nonempty
 subset $U_i \subseteq U$ and has a profit $p_i > 0$; every element $j \in U$ has a weight $w_j > 0$.
 For any nonempty subset $A \subseteq S$, the profit of A is defined as $P(A) = \sum_{i \in A} p_i$,
 250 and the weight is $W(A) = \sum_{j \in \bigcup_{i \in A} U_i} w_j \leq C$. For a given knapsack capacity
 C , The goal of SUKP is to find a subset of items $S^* \subseteq S$, such that $P(S^*)$ is
 maximized and $W(S^*) \leq C$.

Without loss of generality, we suppose that p_i ($i = 1, 2, \dots, n$), w_j ($j =$
 $1, 2, \dots, m$) and C are positive integers, the set family $\{U_1, U_2, \dots, U_n\}$ is

255 a cover of U , where $U_i \subseteq U$ and $U_i \neq \emptyset$; $W(S) > C$, and for $i \in S$,
 $\sum_{j \in U_i} w_j \leq C$. Let $X = (x_1, x_2, \dots, x_n)$ be an n -dimensional 0-1 vector, and
 $A_X = \{i | x_i \in X \wedge x_i = 1, 1 \leq i \leq n\} \subseteq S$. For any i ($i = 1, 2, \dots, n$), $x_i = 1$
 if and only if $i \in A_X$. By the one-to-one relationship between X and A_X , the
 mathematical model of SUKP is represented as:

$$\text{Max } f(X) = \sum_{i=1}^n x_i p_i \quad (7)$$

$$\text{s.t. } W(A_X) = \sum_{j \in \bigcup_{i \in A_X} U_i} w_j \leq C \quad (8)$$

When using GTOA to solve SUKP, every individual is an n -dimensional 0-1
 vector on $\{0, 1\}^n$. It should be noted that any of the n -dimensional 0-1 vectors
 on $\{0, 1\}^n$ is only a potential solution of SUKP, and it is a feasible solution
 only when satisfying the constraint (8), otherwise it is an infeasible solution.
 265 Yichao He et al.[44] proposed a repair and optimization algorithm S-GROA to
 eliminate the infeasible solutions when solving SUKP by EAs. In S-GROA,
 d_j ($j = 1, 2, \dots, m$) denotes the frequency of the element j ($j \in U$) in subsets
 U_1, U_2, \dots, U_n , and $T_i = \sum_{j \in U_i} (w_j / d_j)$ ($i = 1, 2, \dots, n$). On the basis of
 using S-GROA to deal with infeasible solution, the algorithm for solving SUKP
 270 by GTOA can be described as follows:

Algorithm 4. GTOA for SUKP

Input: An instance of SUKP; Parameters NP , MIT , m_1, m_2, \dots, m_n ; Mu-
 tation probability P_m .

Output: An approximate solution (or optimal solution) B and $f(B)$.

275 1 Sorting p_i / T_i ($i = 1, 2, \dots, n$) in descending order. Storing the subscripts
 of ordered p_i / T_i in array $H[1 \dots n]$;
 2 Generate initial population $P(0) = \{X_i(0) \in \{0, 1\}^n \mid 1 \leq i \leq NP\}$
 randomly, and $t \leftarrow 0$;
 3 $(X_i(t), f(X_i(t))) \leftarrow \mathbf{S-GROA}(X_i(t), H[1 \dots n])$, $1 \leq i \leq NP$;
 280 4 while($t < MIT$) do
 5 for $i \leftarrow 1$ to NP do

```

6       $Y \leftarrow X_{p1}(t) \oplus (F(X_{p2}(t) \oplus (-X_{p3}(t))))$ ;
7       $Y \leftarrow \mathbf{SMO}(Y, P_m)$ ;
8       $(Y, f(Y)) \leftarrow \mathbf{S-GROA}(Y, H[1 \dots n])$ ;
285 9      if  $f(Y) > f(X_i(t))$  then  $X_i(t+1) \leftarrow Y$ ;
10      else  $X_i(t+1) \leftarrow X_i(t)$ ;
11  end for
12  Generate  $\mathbf{P}(t+1)$ , and  $t \leftarrow t+1$ ;
13 end while
290 14 Determine  $B$  in  $\mathbf{P}(\mathbf{MIT})$ ;
15 return( $B, f(B)$ ) .

```

Since the time complexity of the *SortAlgorithm* [12] and S-GROA [44] are $O(n \log n)$ and $O(nm)$, respectively, the time complexity of Algorithm 4 is $O(n^3m)$.

3.2. Solving Discounted {0-1} Knapsack Problem by GTOA

295 Guldan [5] first proposed D{0-1}KP and gave its heuristic and deterministic algorithms. Aiyong Rong et al.[6] defined the kernel of D{0-1}KP and discussed the validity of solving D{0-1}KP by deterministic algorithm. Yichao He et al. [45] presented two evolutionary algorithms FireEGA and SecEGA for solving D{0-1}KP based on GA. Furthermore, they studied deterministic algorithms
300 and approximation algorithms of D{0-1}KP in the literature [49], and note that PSO-GRDKP is a high performance evolutionary algorithm for solving D{0-1}KP.

Definition of D{0-1}KP [5,6]: Given a set of n item groups, suppose that each group i ($i = 0, 1, \dots, n-1$) consists of three items: $3i$, $3i+1$ and $3i+2$. The
305 item $3i$ has weight w_{3i} and profit p_{3i} , and the item $3i+1$ has weight w_{3i+1} and profit p_{3i+1} . The first two items $3i$ and $3i+1$ are paired to derive the third item $3i+2$ with profit $p_{3i+2} = p_{3i} + p_{3i+1}$ and the discounted weight w_{3i+2} , which satisfies $w_{3i+2} < w_{3i} + w_{3i+1}$, $w_{3i} < w_{3i+2}$ and $w_{3i+1} < w_{3i+2}$. In each group, at most one of the three items can be selected to be placed in the knapsack with
310 capacity C . The problem is how to select items loaded into the knapsack such

that the total profit is maximized under the condition that the total weight of the selected items does not exceed C .

Without losing generality, we suppose that p_j, w_j ($0 \leq j \leq 3n-1$), and C are positive integers, $w_{3i+2} \leq C$ ($0 \leq i \leq n-1$), and $\sum_{i=0}^{n-1} w_{3i+2} > C$. Two
 315 mathematical models of D{0-1}KP are represented as follows.

The first mathematical model [5,6]:

$$\text{Max } f(X) = \sum_{i=0}^{n-1} (x_{3i}p_{3i} + x_{3i+1}p_{3i+1} + x_{3i+2}p_{3i+2}) \quad (9)$$

$$\text{s.t. } x_{3i} + x_{3i+1} + x_{3i+2} \leq 1, i = 0, 1, \dots, n-1, \quad (10)$$

$$\sum_{i=0}^{n-1} (x_{3i}w_{3i} + x_{3i+1}w_{3i+1} + x_{3i+2}w_{3i+2}) \leq C, \quad (11)$$

$$x_{3i}, x_{3i+1}, x_{3i+2} \in \{0, 1\}, i = 0, 1, \dots, n-1. \quad (12)$$

320 where $X = (x_0, x_1, \dots, x_{3n-1}) \in \{0, 1\}^{3n}$, x_j ($0 \leq j \leq 3n-1$) is used to indicate whether the item j is loaded into knapsack. The item j is loaded into knapsack if and only if $x_j = 1$.

The second mathematical model [45]:

$$\text{Max } f(X) = \sum_{i=0}^{n-1} \lceil \frac{x_i}{3} \rceil p_{3i+|x_i-1|} \quad (13)$$

$$\text{s.t. } \sum_{i=0}^{n-1} \lceil \frac{x_i}{3} \rceil w_{3i+|x_i-1|} \leq C \quad (14)$$

$$325 \quad x_i \in \{0, 1, 2, 3\}, i = 0, 1, \dots, n-1. \quad (15)$$

where $X = (x_0, x_1, \dots, x_{n-1}) \in \{0, 1, 2, 3\}^n$. The integer variable x_i ($0 \leq i \leq n-1$) indicates whether there is an item of the item group i to be loaded into the knapsack. $x_i = 0$ indicates that no items of item group i is loaded into the knapsack; $x_i = 1$ expresses that the item $3i$ is loaded into the knapsack; $x_i = 2$ indicates that the item $3i+1$ is loaded into the knapsack; $x_i = 3$
 330 expresses that the item $3i+2$ is loaded into the knapsack. $\lceil x \rceil$ is top function of x representing the smallest integer not less than x . Obviously, the length of the feasible solution in the second mathematical model of D{0-1}KP is 1/3 that of

the first one. Therefore, when use GTOA to solve D{0-1}KP under the second
 335 mathematical model, it can not only save storage space but also improve the
 algorithm's running speed.

To eliminate the infeasible solutions of D{0-1}KP, we refer to the skill in [49]
 to propose a repair and optimization algorithm D-GROA. Similar to SUKP, sort
 all items of the D{0-1}KP instance according to the order of p_j/w_j ($0 \leq j \leq$
 340 $3n - 1$) from large to small, and store the subscripts of the items into the array
 $H[0 \dots 3n - 1]$ according to the order. Let $X = (x_0, x_1, \dots, x_{n-1}) \in \{0, 1, 2, 3\}^n$
 be a potential solution of the D{0-1}KP instance; $\lfloor x \rfloor$ is the bottom function
 representing the maximum integer not greater than x ; $H[j](mod 3)$ denotes the
 remainder when $H[j]$ is divided by 3. Then, the pseudo-code of D-GROA is
 345 described as follows:

Algorithm 5. D – GROA

Input: A potential solution $X = (x_0, x_1, \dots, x_{n-1}) \in \{0, 1, 2, 3\}^n$ and array
 $H[1 \dots 3n]$.

Output: A feasible solution $X = (x_0, x_1, \dots, x_{n-1})$ and its objective function
 350 value $f(X)$.

```

1   $R \leftarrow \sum_{i=0}^{n-1} \lceil \frac{x_i}{3} \rceil w_{3i+\lfloor x_i-1 \rfloor}; \quad j \leftarrow 3n - 1;$ 
2  while ( $R > C$ ) do //Repair phase
3     $k \leftarrow \lfloor H[j]/3 \rfloor; \quad r \leftarrow H[j](mod 3);$ 
4    if ( $x_k = r + 1$ ) then  $x_k \leftarrow 0$ ;  $R \leftarrow R - w_{H[j]}$ ;
355 5     $j \leftarrow j - 1;$ 
6  end while
7  for  $j \leftarrow 0$  to  $3n - 1$  do //Optimizing phase
8     $k \leftarrow \lfloor H[j]/3 \rfloor; \quad r \leftarrow H[j](mod 3);$ 
9    if ( $x_k = 0$ )  $\wedge$  ( $R + w_{H[j]} \leq C$ ) then
360 10       $R \leftarrow R + w_{H[j]}; \quad x_k \leftarrow r + 1;$ 
11    end if
12 end for
13 return( $X, f(X)$ ).
```

In D-GROA, $f(X) = \sum_{i=0}^{n-1} \lceil \frac{x_i}{3} \rceil p_{3i+|x_i-1|}$ is used as the fitness of X , which
 365 is obtained in Step 13. The time complexity of D-GROA is $O(n)$.

On the basis of using D-GROA to eliminate infeasible solutions, the algorithm for solving D{0-1}KP by GTOA is given as follows.

Algorithm 6. GTOA for D{0-1}KP

Input: An instance of D{0-1}KP; Parameters NP , MIT , m_1, m_2, \dots, m_n ;
 370 Mutation probability P_m .

Output: An approximate solution (or optimal solution) B and $f(B)$.

1 Sort p_j/w_j ($j = 0, 1, \dots, 3n-1$) in descending order. Store the subscripts
 of ordered p_j/w_j in array $H[0 \dots 3n-1]$;
 2 Generating initial population $\mathbf{P}(0) = \{X_i(0) \in \{0, 1, 2, 3\}^n \mid 1 \leq i \leq NP\}$
 375 randomly, $t \leftarrow 0$;
 3 $(X_i(t), f(X_i(t))) \leftarrow \mathbf{D-GROA}(X_i(t), H[0 \dots 3n-1])$, $1 \leq i \leq NP$;
 4 while($t < MIT$) do
 5 for $i \leftarrow 1$ to NP do
 6 $Y \leftarrow X_{p1}(t) \oplus (F(X_{p2}(t) \oplus (-X_{p3}(t))))$;
 380 7 $Y \leftarrow \mathbf{IRMO}(Y, P_m)$;
 8 $(Y, f(Y)) \leftarrow \mathbf{D-GROA}(Y, H[0 \dots 3n-1])$;
 9 if $f(Y) > f(X_i(t))$ then $X_i(t+1) \leftarrow Y$
 10 else $X_i(t+1) \leftarrow X_i(t)$;
 11 end for
 385 12 Generate $\mathbf{P}(t+1)$, and $t \leftarrow t+1$;
 13 end while
 14 Determine B in $\mathbf{P}(MIT)$;
 15 return($B, f(B)$).

Obviously, the time complexity of Algorithm 6 is $O(n^3)$.

390 **3.3. Solving the Bounded Knapsack Problem by GTOA**

The BKP [3] belongs to the third category of KPs. It is defined as follows.
 Let $N = \{1, 2, \dots, n\}$ be a set of n items to be packed into a knapsack of size
 C . For $j = 1, 2, \dots, n$, let p_j , w_j and b_j be the profit, weight and the number

of identical copies available for the j th item, respectively, where C and p_j, w_j ,
 395 b_j are all positive integers. The objective is to fill the knapsack with some
 items from N whose total weight is at most C and such that their total profit
 is maximized. The mathematical model of BKP is shown as follows.

$$\text{Max } f(X) = \sum_{j=1}^n p_j x_j \quad (16)$$

$$\text{s.t } \sum_{j=1}^n w_j x_j \leq C \quad (17)$$

$$0 \leq x_j \leq b_j, x_j \text{ is integer}, j = 1, 2, \dots, n. \quad (18)$$

400 where $X = (x_1, x_2, \dots, x_n) \in \mathbf{Z}[b_1 + 1, b_2 + 1, \dots, b_n + 1]$. None of the copies
 of the j th item is loaded into the knapsack when $x_j = 0$, otherwise x_j copies
 of the j th item are loaded. Obviously, 0-1KP is a special case of BKP when
 $b_j = 1 (j = 1, 2, \dots, n)$. Without loss of generality, suppose there is at least one
 j which satisfies $b_j \geq 2$, $\text{Max}\{b_j w_j \mid 1 \leq j \leq n\} \leq C$ and $\sum_{j=1}^n b_j w_j > C$.

405 Similar to SUKP and D{0-1}KP, we give a repair and optimization algorithm
 B-GROA to handle infeasible solution: Sort all the items in the BKP instance
 according to the order of p_j/w_j ($1 \leq j \leq n$) from large to small, and store
 the subscripts sequentially into the array $H[1 \dots n]$ based on the order. Let
 $X = (x_1, x_2, \dots, x_n) \in \mathbf{Z}[b_1 + 1, b_2 + 1, \dots, b_n + 1]$ denote a potential solution
 410 of BKP. The pseudo-code of B-GROA is described as below.

Algorithm 7. B – GROA

Input: A potential solution $X = (x_1, x_2, \dots, x_n) \in \mathbf{Z}[b_1 + 1, \dots, b_n + 1]$ and
 array $H[1 \dots n]$.

Output: A feasible solution $X = (x_1, x_2, \dots, x_n)$ and its objective function
 415 value $f(X)$.

```

1   $R \leftarrow \sum_{j=1}^n w_j x_j; \quad j \leftarrow n;$ 
2  while  $(R > C)$  do //Repair phase
3      if  $(x_{H[j]} > 0)$  then
4           $temp \leftarrow x_{H[j]};$ 
5           $x_{H[j]} \leftarrow \text{Max}\{0, x_{H[j]} - \lceil (R - C)/w_{H[j]} \rceil\};$ 
    420
```

```

6          $R \leftarrow R - w_{H[j]} * (temp - x_{H[j]});$ 
7     end if
8      $j \leftarrow j - 1;$ 
9 end while
425 10 for  $j \leftarrow 1$  to  $n$  do //Optimizing phase
11     if  $(x_{H[j]} < b_{H[j]}) \wedge (R + w_{H[j]} \leq C)$  then
12          $temp \leftarrow x_{H[j]};$ 
13          $x_{H[j]} \leftarrow \text{Min}\{b_{H[j]}, x_{H[j]} + \lfloor (R - C)/w_{H[j]} \rfloor\};$ 
14          $R \leftarrow R + w_{H[j]} * (x_{H[j]} - temp);$ 
430 15     end if
16 end for
17 return( $X, f(X)$ ).

```

Obviously, the time complexity of B-GROA is $O(n)$.

When solving BKP by GTOA, we apply B-GROA to eliminate infeasible
435 solution, which is similar to the procedure in SUKP and D{0-1}KP. To avoid
duplication, we omit it.

4. Experimental Results and Comparative Studies

As we all know, GA [17,46] is one of the most commonly used classic EAs,
suitable for solving combinatorial optimization problems. BPSO [36] is a simple
440 and effective EAs, and performs excellently when solving D{0-1}KP [49] and
RTVKP [52]. Literature [44] is the only study that uses EAs to solve SUKP,
in which the proposed BABC performs better than GA [17,46], binDE [35],
ABCbin [38], and A-SUKP [50]. To verify the performance of GTOA for solving
KPs, we experimentally conduct a comparison between GTOA and GA, BPSO,
445 BABC, FirEGA[45], and SecEGA[45] for their computational performance.

All experiments are were carried out on Acer Aspire E1-570G with Intel(R)
Core(TM)i5-3337u CPU-1.8GHz, 4GB DDR3 (3.82GB available); the operating
system is Microsoft Windows 8. All algorithms are implemented using C ++,

and the compilation environment is Visual C++ 6.0. The figures are drawn by
 450 the MATLAB7.10.0.499 (R2010a).

4.1. Simulation results for the SUKP instances

4.1.1. Parameters setting of the algorithms

To determine the optimal value of P_m in GTOA, we solve three instances
 $sukp300.285.0.10.0.75$, $sukp300.300.0.10.0.75$, and $sukp285.300.0.10.0.75$ [44]
 455 by GTOA when $P_m=0.005, 0.006, 0.007, 0.008, 0.009, 0.010$, and 0.011 . Each in-
 stance is independently calculated 100 times. According to the box-plots in
 Figure1 ~ 3, it is easy to see that $0.008 \leq P_m \leq 0.009$ is the most reasonable
 choice.

When using GTOA, GA, BPSO, and BABC to solve three kinds of large-scale
 460 SUKP instances [44], the population size of all algorithms is set as $NP = 20$,
 individual encoding is an n -dimensional 0-1 vector, the iteration number is set as
 $MIT = \text{Max}\{m, n\}$, n is the number of items and m is the number of elements,
 S-GROA [44] is used to deal with infeasible solutions. In GTOA, F is a random
 0-1 vector, $P_m = 0.008$. In GA [46], the single point crossover operator, the
 465 uniform mutation operator, and the fitness proportional model are used; the
 crossover probability is $P_c = 0.8$ and the mutation probability is $P_m = 0.01$. In
 BPSO [36], set $W = 1.0$, $C_1 = C_2 = 2.0$, and each dimensional component in
 the n -dimensional real vector is in $[-5.0, 5.0]$. In BABC [44], $a = 5.0$ and the
 threshold value is $limit = \text{Max}\{m, n\}/5$.

4.1.2. Calculation and comparison

In Tables 1~ 3(in Appendix), *CBEST* is the best result currently known
 for the instance. *Best* and *Worst* are the best value and the worst value,
 respectively, obtained by GTOA, GA, BPSO, and BABC when solving every
 instance 100 times independently. *Mean* and *Std* denote the mean value and
 475 the standard deviation, respectively, and *Time* is the average running time that
 each algorithm takes for individually solving every instance.

Figure 1: Boxplots of instance sukp300_285_0.10_0.75 when parameter $P_m = 0.005, 0.006, 0.007, 0.008, 0.009, 0.010$, and 0.011 respectively

Figure 2: Boxplots of instance sukp300_300_0.10_0.75 when parameter $P_m = 0.005, 0.006, 0.007, 0.008, 0.009, 0.010$, and 0.011 respectively

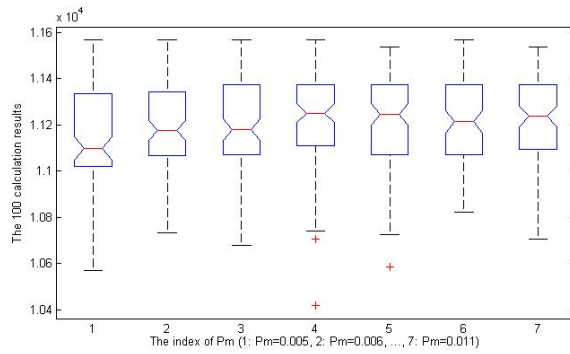

Figure 3: Boxplots of instance sukp285_300_0.10_0.75 when parameter $P_m = 0.005, 0.006, 0.007, 0.008, 0.009, 0.010$, and 0.011 respectively

Figure 4: *Gap* fitting curve of the 1st category of SUKP instances Figure 5: *Gap* fitting curve of the 2nd category of SUKP instances

Figure 6: *Gap* fitting curve of the 3rd category of SUKP instances Figure 7: *StD* histogram of the 1st category of SUKP instances

Figure 8: *StD* histogram of the 2nd category of SUKP instances Figure 9: *StD* histogram of the 3rd category of SUKP instances

Tables 1~3 illustrate that, among the 30 instances, GTOA can achieve the best result currently known of 22 instances, BPSO does that on 5 instances, BABC does that on 2 instances, while GA gets the best result currently known on only one instance. Regarding the average running time, the solving speeds of GA and GTOA are almost equal and obviously faster than those of BPSO and BABC. The difference between the speeds of BABC and BPSO is small.

Since EAs are a type of stochastic approximation algorithms, in order to evaluate its performance, we also need to consider the statistical features of the average performance and stability of all algorithms. Comparisons on the average performance of all algorithms can be conducted by using the *Gap* fitting curves, where the *Gap* metric is the relative difference between the optimal values *OPT* and the mean value *Mean*, whose formulation is given in (19). The closer the *Gap* curve is to the abscissa axis, the better the mean performance of the algorithm is. In addition, we can draw a histogram according to the value of *StD* and evaluate the stability of all algorithms by the distribution of columns.

$$Gap = \frac{|OPT - Mean|}{OPT} \times 100(\%) \quad (19)$$

Since *OPT* of SUKP instances is unknown, *OPT* is replaced by *CBEST* when calculating the *Gap* of GTOA, GA, BPSO, and BABC. The *Gap* curves for each algorithm are given in Figures 4~6, and the histograms of *StD* are drawn in Figures 7~9.

From Figures 4~6, we can see that the performance of GTOA is best in the four algorithms since its average performance is much better than those of GA, BPSO, and BABC; BPSO and BABC rank second; and GA is the worst. Figures 7~9 show that stability of all algorithms are basically equal.

4.2. Simulation results for the $D\{0-1\}$ KP instances

4.2.1. Parameters setting of the algorithms

Using the same method as Section 4.1.1, we find that $P_m = 0.008$ is a suitable value when solving $D\{0-1\}$ KP by GTOA.

FirEGA and SecEGA [45] are the most classic two EAs for solving D{0-1}KP based on GA and different mathematical models. PSO-GRDKP [49] is the most efficient evolutionary algorithm for solving D{0-1}KP currently, which is proposed by using BPSO (we denote PSO-GRDKP as GPSO for convenience). In the following, we will use GTOA, FirEGA, SecEGA, and GPSO to solve four kinds of large-scale D{0-1}KP instances [45]: UDKP1~UDKP10, WDKP1~UDKP10, SDKP1~UDKP10, IDKP1~UDKP10, and evaluate the performance of GTOA by the comparative results.

FirEGA and GPSO use GR-DKP [49] to deal with infeasible solutions. GTOA and SecEGA apply D-GROA to handle infeasible solutions. The iteration number of all algorithms is set as $MIT = 10 * n$, where n is the number of item groups. In GTOA, the population size is set as $NP = 20$; $P_m = 0.008$. The population size of FirEGA and SecEGA are set as $NP = 50$; the others parameters are set to be equal to those in the literature [45]. In GPSO [49], the population size is set as $NP = 20$; each dimensional component in the $3n$ -dimensional real vector takes value in $[-5.0, 5.0]$; $W = 1.0$ and $C_1 = C_2 = 2.0$.

4.2.2. Calculation and comparison

All experimental results are based on 100 independent runs. In Tables 4~7 (in Appendix), OPT is the optimal value; $Best$ and $Worst$ represent the best and worst values among 100 calculated results respectively, and $Mean$ and Std are the expectation and the standard deviation, respectively; Gap is the relative differences between $Mean$ and OPT for each instance, which can be calculated by (19).

From the Gap in Tables 4~7 we can know that the Gap metrics for all algorithms are no more than 18.00, which illustrates that it is not only feasible but also highly efficient to solve D{0-1}KP by using GTOA, FirEGA, SecEGA, and GPSO. Furthermore, the comparison between the $Best$ and $Worst$ of all algorithms shows that, except the instance IDKP1, the $Worst$ obtained by GTOA and GPSO compared to the other 39 instances are better than the $Best$ gained by FirEGA and SecEGA, which indicates that the performances of

GTOA and GPSO for solving D{0-1}KP are much better than those of FirEGA and SecEGA. Therefore, we only need to compare GTOA with GPSO in terms of the average performance and the stability to verify the efficient performance of GTOA.

The *Gap* fitting curves of GTOA and GPSO in Figures 10~13 show that the maximum value of *Gap* for GTOA is no more than 0.4 and that for GPSO it is no more than 1.2, which illustrates that the average performances of both algorithms for solving D{0-1}KP are excellent. Moreover, for UDKP, WDKP and SDKP, it is obvious that the average performance of GTOA is much better than that of GPSO, but for IDKP, GPSO is slightly better than GTOA.

It can be known from the *Std* histograms of GTOA and GPSO in Figures 14~ 17 that for UDKP, WDKP and SDKP, the algorithm stability of GTOA is better than that of GPSO, while for IDKP, GPSO is better.

The above comparative results indicate that the performances of both GTOA and GPSO are much better than those of FirEGA and SecEGA. Moreover, for UDKP, WDKP, and SDKP, GTOA has the best averaged performance and stability. It confirms that solving D{0-1}KP by GTOA is not only feasible but also highly efficient.

4.3. Simulation results for BKP instances

Among the current EAs, GA [17,46] is the only algorithm suitable for solving BKP since the feasible solutions of BKP are denoted as integer vectors in $\mathbf{Z}[b_1 + 1, b_2 + 1, \dots, b_n + 1]$, where $b_j (1 \leq j \leq n)$ is a positive integer. Therefore, we verify the performance of GTOA by experimentally comparing GTOA with GA for solving large-scale BKP instances.

So far there has not yet been a report of benchmark for BKP. We generate three kinds of large-scale BKP instances according to the method in [3].

(1) Uncorrelated instances of BKP(UBKP): p_j and w_j are randomly distributed in $[1, R]$, $1 \leq j \leq n$.

(2) Weakly correlated instances of BKP (WBKP): w_j randomly distributed in $[1, R]$, and p_j randomly distributed in $[w_j - \frac{R}{10}, w_j + \frac{R}{10}]$ such that $p_j \geq 1$.

Figure 10: *Gap* fitting curve of UDKP1~10

Figure 11: *Gap* fitting curve of WDKP1~10

Figure 12: *Gap* fitting curve of SDKP1~10

Figure 13: *Gap* fitting curve of IDKP1~10

Figure 14: *StD* histogram of UDKP1~10

Figure 15: *StD* histogram of WDKP1~10

Figure 16: *StD* histogram of SDKP1~10

Figure 17: *StD* histogram of IDKP1~10

(3) Strongly correlated instances of BKP (SBKP): w_j randomly distributed
 565 in $[1, R]$ and $p_j = w_j + 10$.

In all instances, $R = 1000$ and $C = 0.55 * \sum_{j=1}^n w_j b_j$, where $b_j (1 \leq j \leq n)$ is randomly distributed in interval $[1, 9]$. For more details of the BKP instances, please refer to <http://xxgc.hgu.edu.cn/uploads/heyichao/ThreekindsofBKPInstances.rar>.

When using GA and GTOA to solve BKP, the iteration number is set as
 570 $MIT = 2n$, n is the number of items, and we use B-GROA to eliminate infeasible solutions. In GTOA, the population size is $NP = 20$, and we use RLCO and IRMO to generate new individuals; $P_m = 0.001$. In GA, the population size is $NP = 50$; we use single-point crossover, uniform mutation operators, and fitness proportional model to generate new individuals; $P_c = 0.8$ and $P_m = 0.001$.

575 In Tables 8~10 (in Appendix), OPT is the optimal value of instance; $Best$ and $Worst$ represent the best and worst values, respectively, obtained by using GTOA and GA in 100 independent runs, and $Mean$ and StD are the mean value and standard deviation, respectively.

Table 8~10 illustrate that in terms of $Best$ and $Worst$, the absolute error
 580 $|OPT - Worst|$ between $Worst$ and OPT is no more than 117. In addition, for 4/5 of all BKP instances, the OPT can be attained by both algorithms, which indicates that the average performances of both GA and GTOA are excellent. Noting that the StD values of both GA and GTOA are no more than 27, we believe that both of GA and GTOA have very good stability.

585 Although both GA and GTOA perform well for solving BKP, the indexes in Tables 8~10 show that GTOA performs better when GTOA is used to solve the UBKP instances, and GA is better than GTOA for the SBKP instances. For the WBKP instances, both algorithms perform similarly. In summary, GTOA and GA have the same performance for solving BKP. They can efficiently solve
 590 BKP.

5. Conclusion

This paper presents an algebraic approach for designing evolutionary algorithms and proposes a new evolutionary algorithm GTOA by using the direct product of groups. To verify GTOA's effectiveness and wide range of applications, we apply it to solve different KPs, i.e., SUKP, D{0-1}KP, and BKP. In comparison with GA, BPSO, GPSO, BABC, FirEGA, and SecEGA for large-scale instances of KPs, we conclude that GTOA is not only easy to implement but also performs much better.

Some remarks and further investigations in this topic are listed: First, using the operations of a group to implement evolution search is a new and feasible evolution search mechanism. It is not only the innovation of algorithm design method but is also a successful paradigm for designing evolutionary algorithms by using the strict algebra theory. Second, the proposed GTOA is suitable not only for KPs but also for the others combinatorial optimization problems, for example, the satisfiability problem [27], the set cover problem [28,53], the decision making problem [54,55], and the machine scheduling problem [56]. Therefore, using GTOA to solve others combinatorial optimization problem is an important research topic. Finally, how to use GTOA to solve numerical optimization problems [57], topology optimization problem [58-60], feature selection problem [61], and semi-supervised clustering [62] is another topic which is worth researching in the future.
